CSE 453 High Performance Database System

Dr. Abu Sayed Md. Latiful Hoque Professor, CSE, BUET

Contact: mobile 01556346357

email: asmlatifulhoque@cse.buet.ac.bd

About Course

Course Summary:

- Parallel Database Architecture, partitioning, replication, indexing and Query processing
- Distributed Database Architecture, Storage and Query processing, transaction management, concurrency control and Design
- 3. Query optimization in centralized and distributed database
- High performance data models: NoSQL, semi-structured and column-oriented etc.
- Big data and Data Analytics: overview, Data warehousing: Storage structure and star schema, design and OLAP

Books

Text books:

```
Database System Concepts 7<sup>th</sup> Edition

By

Abraham Silberschatz, Henry F. Korth, S. Sudarshan,
```

Reference books:

Fundamentals of Database Systems 7th Edition By

Ramez Elmasri and Shamkant B. Navathe

Weightage Distribution among Assessment Tools

- As per academic council guidelines
- Class performance
- Assignment on Data Analytics
- Assignment on High Performance Data Models
- Class Tests
- Final Examination

Tentative Mode of Online Class

Lecture will be interactive using ppt slides.

- 1.After a few slides, there shall be some analytical questions to answer or some problems to solve.
- 2.Each student must write the answer in A4 size white paper with black ball point pen clearly and chronologically.
- 3. The answer of the questions or the solution of the problems will be discussed and guided so that the students can write answer/solve the question/problem.
- 4.At the end of the class, students will be given some time to upload the scanned/image of the sheets as per moodle requirements.
- 5. These uploads will be considered as class performance.

Basic towards High Performance DBMS

- What you have leant in Basic DBMS?
 - Data model Relational model
 - 2. Query Languages
 - 4 Relational Algebra
 - 4 Relational Calculus
 - 4 SQL
 - Database Design (ERD)
 - 4. Refinement of Database Design (Normalization)

Basic towards High Performance DBMS

- What you have learnt in Basic DBMS?
 - Database Storage Management -> High Performance
 - Indexing -> High Performance
 - Query Processing and Optimization -> High Performance
 - 8. Transaction management -> High Performance
 - Concurrency Control of Transactions -> High Performance
 - 10. Distributed Database
 - 11. -> High Performance Data Models

Classification of Physical Storage Media

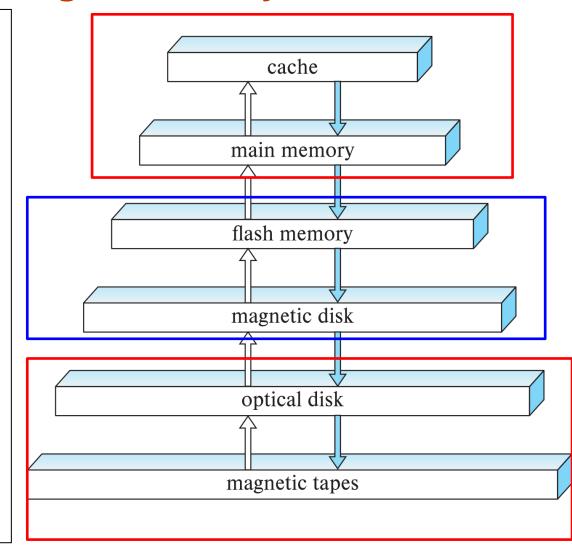

- Can differentiate storage into:
 - volatile storage: loses contents when power is switched off
 - non-volatile storage:
 - 4 Contents persist even when power is switched off.
 - Includes secondary and tertiary storage, as well as batterbacked up main-memory.
- Factors affecting choice of storage media include
 - Speed with which data can be accessed
 - Cost per unit of data
 - Reliability

Storage Hierarchy

primary storage: Fastest media but volatile (cache, main memory).

secondary storage: next level in hierarchy, non-volatile, moderately fast access time Also called on-line storage E.g., flash memory, magnetic disks

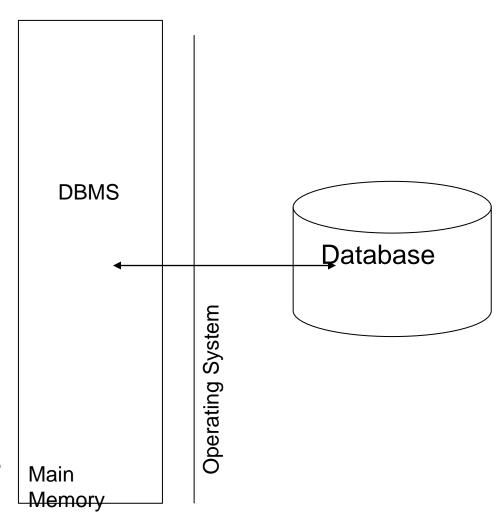

tertiary storage: lowest level in hierarchy, non-volatile, slow access time also called off-line storage and used for archival storage e.g., magnetic tape, optical storage

DBMS System Architecture

- Main Memory DBMS
- Disk-Based DBMS

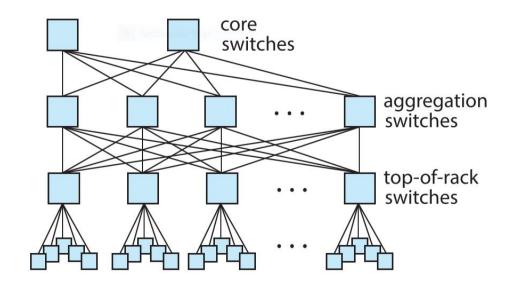

Question 1-1: Explain the implications of storage to MMDBMS and Disk-based DBMS

Parallel Database System Architecture (Data Center Server System)

Tree-like or Fat-Tree Topology:

- widely used in data centers today
- DC are typically mounted in racks
- Each rack has approx. 40 nodes
- Top of rack switch for approx 40 machines in rack
- Each top of rack switch connected to multiple aggregation switches.
- Aggregation switches connect to multiple core switches.

(e) tree-like topology

Parallel Systems

- Parallel database systems consist of multiple processors and multiple disks connected by a fast interconnection network.
- Motivation: handle workloads beyond what a single computer system can handle
- High performance transaction processing
 E.g. handling user requests at web-scale
- Decision support on very large amounts of data
 E.g. data gathered by large web sites/apps

Parallel Systems (Cont.)

- A coarse-grain parallel machine consists of a small number of powerful processors
- A massively parallel or fine grain parallel machine utilizes thousands of smaller processors.
 Typically hosted in a data center
- Two main performance measures:
 throughput --- the number of tasks that can be completed in a given time interval response time --- the amount of time it takes to complete a single task from the time it is submitted

Speed-Up

speed

Speedup: a fixed-sized problem executing on a small system is given to a system which is *N*-times larger.

Measured by

Speed up =
$$\frac{small\ system\ elapsed\ time}{large\ system\ elapsed\ time}$$

Speedup is linear if equation equals N.

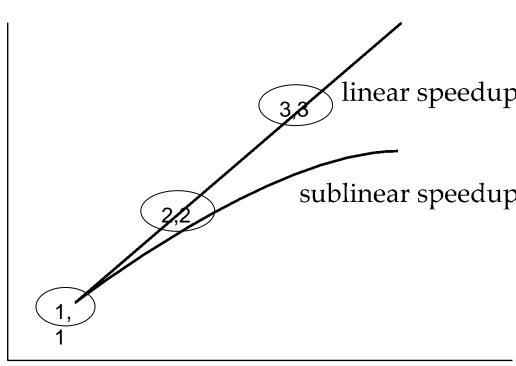

Example: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

1. The number of node has been increased to 2.

The time is 5ms. Speed up = 10/5 = 2

2. The number of node has been increased to 3. The time is 3.333ms. Speed up = 10/3.33 = 3

Linear Speed up 1, 2, 3 ...

resources ----

Speed-Up

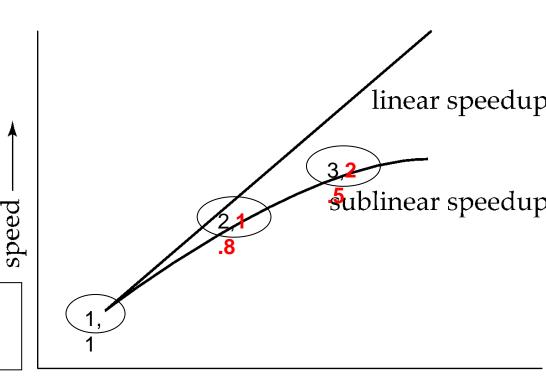

Speedup: a fixed-sized problem executing on a small system is given to a system which is *N*-times larger.

Measured by

Speed up =
$$\frac{small\ system\ elapsed\ time}{large\ system\ elapsed\ time}$$

Speedup is linear if equation equals N.

Example: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

- The number of node has been increased to 2. The time is 5.55ms. Speed up = 10 / 5.55 = 1.8
- 2. The number of node has been increased to 3. The time is 4ms. Speed up = 10/4 = 2.5

SubLinear Speed up 1, 2, 3 ...

resources ----

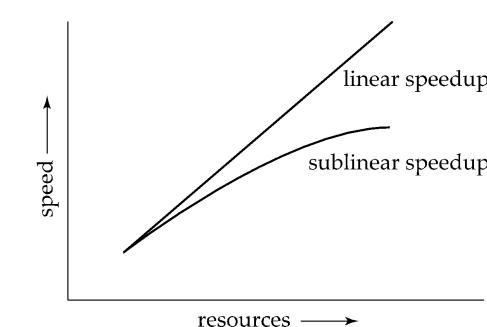

Speed-Up

Speedup: a fixed-sized problem executing on a small system is given to a system which is *N*-times larger.

Measured by

Speed up = $\frac{small\ system\ elapsed\ time}{large\ system\ elapsed\ time}$

Speedup is linear if equation equals N.

Question 2-1: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

- 1. The number of node has been increased to 2. The time to solve P is 5ms
- 2. The number of node has been increased to 3. The time to solve P is 4ms
- 3. The number of node has been increased to 4. The time to solve P is 3ms

Find the type of speedup graph for the above system and explain.

Scaleup: increase the size of both the problem and the system *N*-times larger system used to perform *N*-times larger

Measured by:

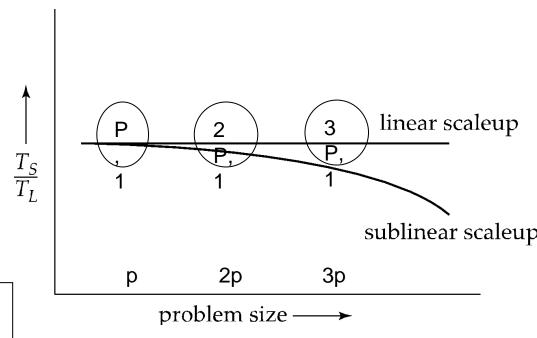

job

Scale up = small system small problem elapsed time big system big problem elapsed time

Scale up is linear if equation equals 1.

Example: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

Scale-Up

- 1. The number of node has been increased to 2. The size of the problem = 2p, elapsed time = 10ms, Scale up = 10/10 = 1
- 1. The number of node has been increased to 3. The size of the problem = 3p, elapsed time = 10ms, Scale up = 10/10 = 1

Linear Scale up

size of both the

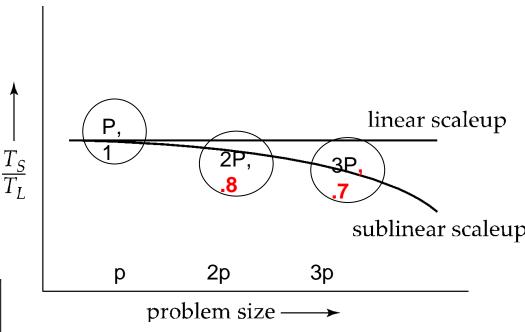

Scaleup: increase the size of both the problem and the system *N*-times larger system used to perform *N*-times larger job

Measured by:

Scale up = <u>small system small problem elapsed time</u> <u>big system big problem elapsed time</u>

Scale up is linear if equation equals 1.

Example: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

- The number of node has been increased to 2.
 The size of the problem = 2p, elapsed time = 12ms, Scale up = 10/12 = 0.8
- 2. The number of node has been increased to 3. The size of the problem = 3p, elapsed time = 14 ms, Scale up = 10/14 = 0.7

SubLinear Scale up

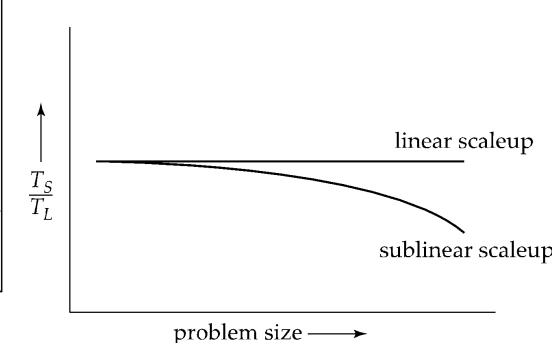

Scaleup: increase the size of both the problem and the system *N*-times larger system used to perform *N*-times larger job

Measured by:

Scale up = <u>small system small problem elapsed time</u> <u>big system big problem elapsed time</u>

Scale up is linear if equation equals 1.

Scale-Up

Question 2-2: A server system has 1 node (small system) and elapsed to solve problem P is 10ms.

- 1.The number of node has been increased to 4.The size of the problem = 4p, elapsed time is 40ms
- 2. The number of node has been increased to 8. The size of the problem = 8p, elapsed time is 80ms

Find type of scale up graph for the above system and explain

Speedup and scaleup are often sublinear due to:

Startup/sequential costs: Cost of starting up multiple processes, and sequential computation before/after parallel computation

May dominate computation time, if the degree of parallelism is high

Suppose sequentially, a task completion time = T

Fraction of T that can be executed parallel by n nodes = p

Sequential time =
$$(1-p)T$$
 Parallel time = $(pT)/n$
Elapsed time = $(1-p)T + pT/n$

Amdahl's law: speedup =
$$\frac{T}{(1-p)T + pT/n}$$

$$=\frac{1}{(1-p)+p/n}$$

Suppose sequentially, a task completion time = T

Fraction of T that can be executed parallel by n nodes = p

Sequential time =
$$(1-p)T$$
 Parallel time = $(pT)/n$
Elapsed time = $(1-p)T + pT/n$

Amdahl's law: speedup =
$$\frac{T}{(1-p)T + pT/n}$$

$$=\frac{1}{(1-p)+p/n}$$

Question 2-3: Explain speedup as per Amdahl's law for the following cases:

- Case 1: Full fraction of T can be executed in parallel (p = 1)
- Case 2: No fraction of T can be executed in parallel (p = 0)
- Case 3: A fraction of T can be executed in parallel (0

Speedup and scaleup are often sublinear due to:

Startup/sequential costs: Cost of starting up multiple processes, and sequential computation before/after parallel computation

May dominate computation time, if the degree of parallelism is high

Suppose sequentially, a task completion time = T

Fraction of T that can be executed parallel by n nodes = p

Problem size = nT

Sequential time =
$$(1-p)nT$$

Sequential time = (1-p)nT Parallel time = (pnT)/n = pT

Elapsed time = (1-p)nT+pT

Gustafson's law: scaleup =
$$\frac{T}{(1-p)nT + pT}$$

$$=\frac{1}{(1-p)n+p}$$

Suppose sequentially, a task completion time = T

Fraction of T that can be executed parallel by n nodes = p

Problem size = nT

Sequential time = (1-p)nT

Parallel time = (pnT)/n = pT

Elapsed time = (1-p)nT+pT

Gustafson's law: scaleup =
$$\frac{T}{(1-p)nT + pT}$$

= $\frac{1}{(1-p)n + p}$

Question 2-2: Explain scaleup as per Gustafson's law for the following cases:

Case 1: Full fraction of T can be executed in parallel (p = 1)

Case 2: No fraction of T can be executed in parallel (p = 0)

Speedup and scaleup are often sublinear due to:

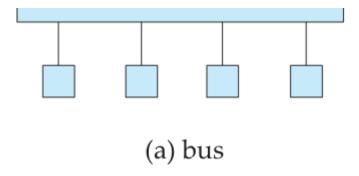

Interference: Processes accessing shared resources (e.g.,system bus, disks, or locks) compete with each other, thus spending time waiting on other processes, rather than performing useful work.

Skew: Increasing the degree of parallelism increases the variance in service times of parallely executing tasks. Overall execution time determined by **slowest** of parallely executing tasks.

Interconnection Network Architectures

Bus. System components send data on and receive data from a single communication bus;

Does not scale well with increasing parallelism.

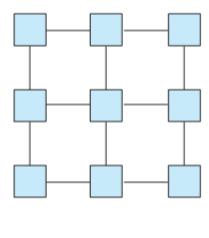

Interconnection Network Architectures

Mesh. Components are arranged as nodes in a grid, and each component is connected to all adjacent components

Communication links grow with growing number of components, and so scales better.

But may require $2(\sqrt{n-1})$ hops to send message to a node

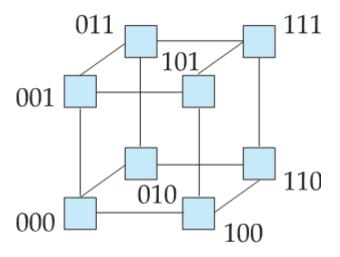

(c) mesh

Interconnection Network Architectures

Hypercube. Components are numbered in binary; components are connected to one another if their binary representations differ in exactly one bit.

Each of n components are connected to log(n) other components and can reach each other via at most log(n) links; reduces communication delays.

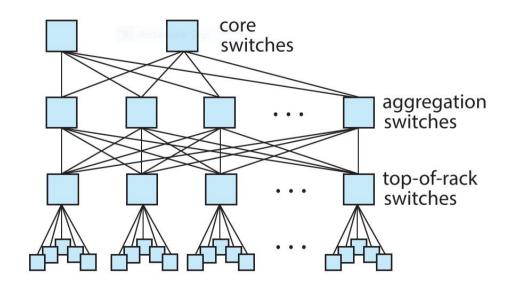

(d) hypercube

Interconnection Network Architectures (Data Center Server System)

Tree-like or Fat-Tree Topology:

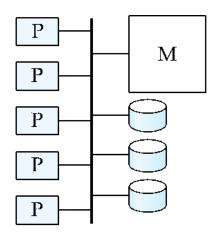

- widely used in data centers today
- DC are typically mounted in racks
- Each rack has approx. 40 nodes
- Top of rack switch for approx 40 machines in rack
- Each top of rack switch connected to multiple aggregation switches.
- Aggregation switches connect to multiple core switches.

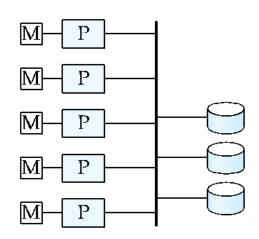

(e) tree-like topology

Question 3-1: Discuss comparative advantages and Disadvantages of BUS, Mesh, Hypercube and Tree topology.

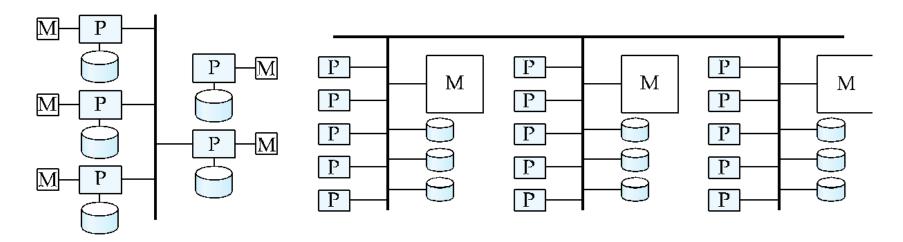

Parallel Database Architectures

(a) shared memory

(b) shared disk

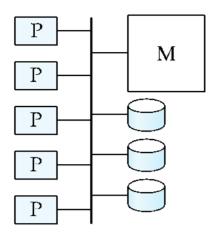

(c) shared nothing

(d) hierarchical

Shared Memory

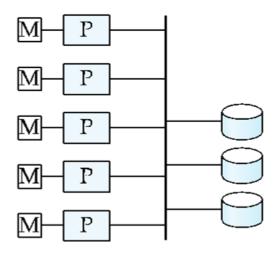

- Processors (or processor cores) and disks have access to a common memory
 - Via a bus in earlier days, through an interconnection network today
- Extremely efficient communication between processors
- Downside: shared-memory architecture is not scalable beyond 64 to 128 processor cores
 - Memory interconnection network becomes a bottleneck

(a) shared memory

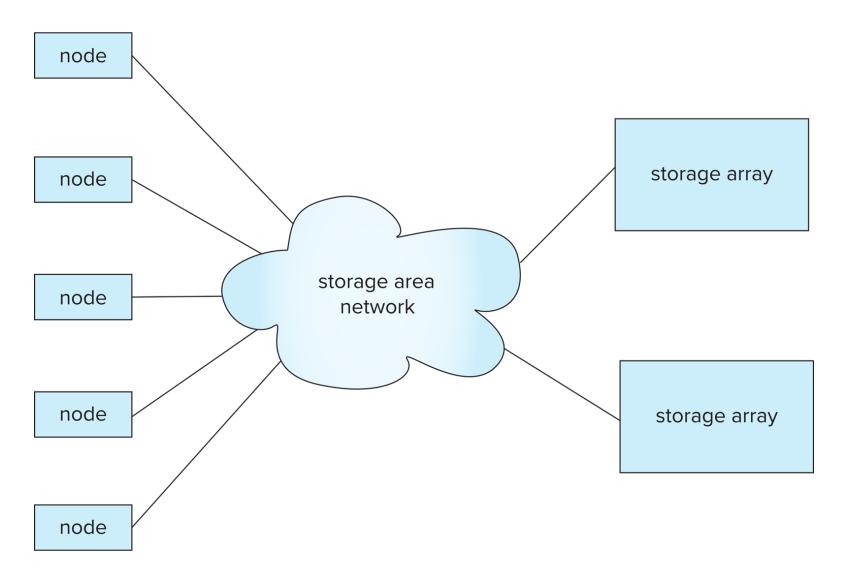

Shared Disk

- All processors can directly access all disks via an interconnection network, but the processors have private memories.
 - Architecture provides a degree of fault-tolerance — if a processor fails, the other processors can take over its tasks
 - 4 the data of the failed processor is resident on disks that are accessible from all processors.
- Downside: bottleneck now occurs at interconnection to the disk subsystem.

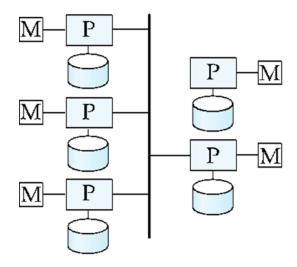

(b) shared disk

Modern Shared Disk Architectures: via Storage Area Network (SAN)

Shared Nothing

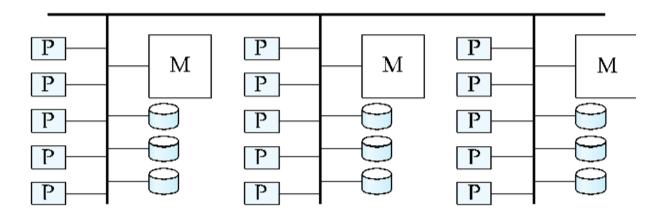

- Node consists of a processor, memory, and one or more disks
- All communication via interconnection network
- Can be scaled up to thousands of processors without interference.
- Main drawback: cost of communication and non-local disk access; sending data involves software interaction at both ends.

(c) shared nothing

Hierarchical

- Combines characteristics of shared-memory, shared-disk, and shared-nothing architectures.
 - Top level is a shared-nothing architecture
 - 4 With each node of the system being a shared-memory system
 - Alternatively, top level could be a shared-disk system.
 - 4 With each node of the system being a shared-memory system

(d) hierarchical

Question 3-2: Show the hierarchical architecture with top level be a shared-disk system and each node of the system being a shared-memory system.

Shared-Memory Vs Shared-Nothing

- Shared-memory internally looks like shared-nothing!
 - Each processor has direct access to its own memory, and indirect (hardware level) access to rest of memory
 - Also called non-uniform memory architecture (NUMA)
- Shared-nothing can be made to look like shared memory
 - Reduce the complexity of programming such systems by distributed virtual-memory abstraction
 - Remote Direct Memory Access (RDMA) provides very lowlatency shared memory abstraction on shared-nothing systems
 - 4 Often implemented on top of infiniband due it its very-lowlatency
 - But careless programming can lead to performance issues
